II. SUBJECT INDEX

KEY

In using this index the following should be borne in mind:

1. Subjects, not words, have been indexed.

2. Abstracts, not merely their titles, have been considered in indexing.

3. The small superior numeral which accompanies each reference number designates the fraction of the column in ninths in which the subject being indexed is first considered.

4 "P" before a column number indicates that the abstract is of a patent.

5. The alphabeting of index headings has been done on the basis first of that part which comes before the comma in such headings as *Copper, metallurgy of* and *Phenol, p-nitro-*. E. g., these headings come before the headings *Copper compounds* and *Phenol condensation products*, respectively.

6. Organic compounds are indexed on the basis of "parent compounds," or more accurately, "index compounds" (see Introduction), the names of substituent radicals following in alphabetical order. The system of naming organic compounds which has been used is outlined in the Introduction below Esters and salts of organic acids are, in general, indexed under the names of the acids; notes in the index under the appropriate headings explain the few exceptions.

7. An asterisk (*) following the name of an organic compound entered in the index signifies that the name, or numbering, or both are the author's own and may not conform to the system of nomenclature used in this index. This sign is used where it has seemed inadvisable, owing to incomplete information, to attempt to make the name conform to the system, or where the author's name, differing widely from the one given to the compound by the indexer, is given as an extra entry.

8. A dagger (†), which follows the names of a few compounds, signifies that the entry is an extra one, the name being only slightly less favored than the one chosen for the other entry. The preferred name can be determined by reference to the Formula Index

The desirability of making the index readily usable without the need of reference to an elaborate introduction has been held constantly in mind Although an introduction seems desirable and should be helpful, nevertheless the index is dependent neither on the Key nor on the Introduction. Numerous cross references are given throughout the index, and notes appear in connection with certain headings. An examination of the Introduction, which follows, should be especially helpful to those interested in looking up organic compounds

INTRODUCTION

General policy. The indexing of subjects, as opposed to word indexing, has been emphasized This avoids omissions, scattering and unnecessary entries, with the abundant cross references used it means that one should be able to find all of the references on any subject with certainty and with a minimum of effort The words used as subject headings or modifying phrases are not necessarily to be found in the abstracts but an expression of the idea suggested will be found within or beginning in the ninth of the column designated by the small superior numeral following the column number Chemical compounds have been named and entered systematically, the system used is outlined below All new compounds and all elements, compounds and other substances for which new data are given have been indexed, with the single exception of new compounds for which no names or structures have been given Such compounds are entered only in the Formula Index The Subject Index is in no other respect altered because of the Formula Index

Modifying phrases. In writing such phrases for the entries under any heading the words have been arranged so that the idea considered to be the most important is ex-

pressed at the beginning whenever feasible and this procedure, as well as the selection of the words for this purpose, has been governed by numerous formulated general principles and specific rules E g, "detection of" has been used consistently whenever correct at the beginning of the modifications in indexing subjects treated from a qualitative analytical point of view, instead of permitting a scattering under such additional phrases as "test for," 'reaction for," etc, regardless of what words may have been used in the text In the case of appropriate headings the selection of first words for modifications has been made on the basis of a definite system of classification In alphabeting modifying phrases prepositions at the beginning have been ignored

Inorganic compounds. Simple inorganic compounds have been entered under the usual names With the exception of a few common compounds, such as carbon dioxide and carbon monoxide, compounds of a given element with another or with a definite radical, which differ only in valence relations with regard to the cations, have been grouped E g, the various oxides of nitrogen are grouped under the heading "*Nitrogen oxides*" and classified there, bold face formulas being used as subheadings, and for compounds of iron, gold, copper and tin such headings as *Iron sulfates*, under which the 'ous" and "ic" salts are entered, have been used rather than headings beginning with 'ferric(ous)," "auric(ous)," "cupric(ous)" or "stannic-(ous)"

Acid salts and many basic salts have been grouped under the simple names for the neutral or normal salts, e g, *Calcium phosphates*, *Copper chlorides*, also with the use of bold face formulas as subheadings In certain cases, basic salts have been entered under names such as *Bismuth oxynitrate* and *Uranyl nitrate* Class names such as *Bicarbonates* have been used as headings

In many instances (guiding cross references have been entered) acids and salts have been grouped under such headings as *Silicic acids* or *Calcium aluminates* with the avoidance of headings with prefixes such as meso-, meta-, ortho-, para, pyro-, di, tri and poly-

For binary compounds and mixed halides the order of decreasing electropositivity for nonmetallic elements given in the report of the German Commission for Nomenclature[1] has been followed Sb, As, V, Si, C, P, Te, Se, S, I, Br, Cl, N, O, F, except that the headings *Fluorine oxides*, *Nitrogen chloride*, *Nitrogen iodide*, etc, have been used

Binary compounds of hydrogen have been indexed for the most part under the names most commonly used, e g, *Arsine*, *Borane* and *Boron hydrides*, *Hydrochloric acid* and *Hydrogen sulfide*

Complex inorganic compounds which cannot be given definite names satisfactory for index entries have usually been indexed under the heading which represents the class of compounds concerned and under a heading based on the name of the significant element Ammino compounds have been treated in this manner: in addition to the significant-element entry an entry has been made at *Ammino compounds* or in some cases at the heading for the specific organic base that may play the same role as NH_3 I, g, tetrammmecupric sulfate would be indexed under *Ammino compounds* and under *Copper compounds*, and $[Ag(C_{12}H_8N_2)_2]NO_3 H_2O$ under *1,10-Phenanthroline* and *Silver compounds* The headings *Acetato compounds* and *Oxalato compounds* have been used for entries for specific compounds, but similar special treatment has not been extended to other acid radicals grouped around the central coördinating elements For many compounds of intermediate complexity with names that might be considered suitable for index entries but that are not generally recognized, two or more entries have been made, as under such a general heading as *Chromium compounds* and under the specific acid or salt name used by the author or selected as suitable E g, entries would be made at both *Rhodium compounds* and *Potassium fluorhodite* for K_3RhF_6, and at *Copper compounds*, *Tartaric acid* and *Sodium cuprotartrate* for $NaCuC_4H_4O_6 2H_2O$ For complexes of the better-known types such as chloroplatinates, fluoberyllates and phosphomolybdates, entries have been made only at the names of the specific compounds For the relatively simpler coordinated compounds containing the halogens, the cyano group or any of a few other groups, names have been favored with endings derived from the central coordinating element except for such well-established names as cobaltic and cobalto-cyanide, cobaltic- and cobaltonitrite and ferri- and ferro-cyanide E g, chloroplatinate, chloroplatinite, cyanoargentate and nitronickelate(II) have been preferred to platinichloride, platinochloride, argentocyanide and nickelonitrite, respectively (a Roman numeral has been used with an invariable -ic or -ate ending to denote the valency of the central coördinating element in a few cases in which no corresponding well-established oxygen acids are known) In still other instances compounds have been named as double salts where such names seemed more suitable, with double entries for those with two cations (e g, at *Ammonium magnesium phosphate* and *Magnesium ammonium phosphate*) and with single entries for those with two anions, the anions being given in alphabetical order (e. g, *Calcium aluminate sulfate*)

In general, the chief determining factors in the selection of names have been conformity with usage and with indexing policy Cross references have been entered and formulas introduced wherever they might prove helpful The Formula Index, which follows the Subject Index, should be particularly helpful in locating complex compounds

Deuterium compounds. These have been named for indexing by the modified Boughton system favored by the Nomenclature, Spelling and Pronunciation Committee of the American Chemical Society[1] According to this system the substitution of deuterium for hydrogen in a compound is designated by the use of *d* following the common name for the hydrogen compound as shown by the following examples

NH_3D	ammonia-*d*
NH_2D_2	ammonia-d_2
ND_3	ammonia-d_3
$CH_3CO\text{-}D$	acetic acid-*d*
CD_3CO_2D	acetic-d_4 acid-*d*
CH_3D	methane-*d*
CD_3Br	methane *d*-, dibromo

[1] Meyer *Helv Chim Acta* **20**, 159–73 (1937)

[1] Crane *Science* **80** 89–91 (1934)

This method serves to keep the deuterium compounds close to the corresponding hydrogen compounds in the index. It also avoids the longer and sometimes confusing names arrived at by the use of "deuterio-" in the manner commonly employed in organic chemistry to designate substituents The modified Boughton names depart least from established nomenclature, are suitable for both inorganic and organic compounds, contributed to ease of thinking, are convenient for other use as well as indexing and fit the conception that compounds containing deuterium are after all compounds of a form of hydrogen It has been found that the "deuterio-" system results in many strange names which have to be deciphered only to find the compounds old friends in disguise With D used as the symbol for deuterium, cross references from the Formula Index to the Subject Index have been used or complete entries have been made.

Organic compounds. Except for the modifications listed in the Note below, the system used for naming and indexing organic compounds is the same as that in use starting with the 1916 volume. An explanation of it by Austin M. Patterson and Carlton E. Curran, who are its originators, has appeared in another journal of the Society [1] The system is based on existing usage and follows this as far as is practicable, so that a great many familiar names are unaffected Only the general principles will be given here, but in the index itself will be found abundant cross references and also notes under *Alcohols, Ketones,* etc , indicating how compounds of these classes are named [2]

1 The "chief function" of a compound is expressed *in the main part of the name* wherever possible, and not as a substituent, thus: Pyrrolecarboxylic acid, not carboxypyrrole, ethyl alcohol or ethanol, not hydroxyethane; pentanone, not oxopentane.

2 In compounds of mixed function, the chief function is determined from the following order of precedence[3]: *"onium" compounds, acid* (carboxylic first), *acid halide, amide, imide, aldehyde, nitrile, ketone, alcohol, phenol, thiol, amine, imine, ether, sulfide* (and *sulfoxide* and *sulfone*) Thus, hydroxybenzonitrile, not cyanophenol, aminophenol, not hydroxyaniline

3 A multiple chief function is expressed where feasible as -diol, -dicarboxylic acid, etc , rather than as hydroxy—ol, carboxy—acid, etc. But amino and imino groups attached to cyclic bases are treated as substituents, as, aminopyridine

4 The index compound should be as large, and the substituents as small, as is practicable in conformity with the above rules; as, ethylbenzene, not phenylethane But such names as diphenylethane and triphenylmethanol are exceptions When the chief function is in a side chain attached to a complex nucleus, "additive" names are preferred in order to harmonize 1 and 4, thus, naphthaleneacetic acid, not naphthylacetic acid (with the result that the compound is indexed with other naphthalene derivatives instead of under acetic acid; see 5).

5 The main part of the name with its functional ending, if any, is placed *first* in the index, the names of substituents following, thus, chloroacetic acid would appear in the index as *Acetic acid, chloro-* and dihydroxyanthraquinone as *Anthraquinone, dihydroxy-*. The part thus placed first is called the "index compound"; it may or may not be the "parent compound" (in the second example the parent compound is anthracene)

6 Names in which two functions are expressed in the index compound, as propanolone, cyclopentanonecarboxylic acid, are avoided, except that a few very common ones such as phenolsulfonic acid, are used (indicated by cross references)

7 The names of the substituent radicals in the name of a compound are arranged *in alphabetical order*, as, benzylethylmethylphenylammonium chloride The number of radicals of each kind does not affect the order (e g , *benzyl* precedes *ethyl* no matter how many of each are present), but the compound name of a substituted radical is treated as a unit with its own alphabetic position, thus *dimethyl amino* , Me_2N, follows *benzyl* but precedes *ethyl* When the complete name has been formed, it is alphabeted as any *other word*

8 Parentheses, brackets and even braces are used where necessary to mark off complex radical names.

9 Arabic numerals are given preference for numbering, although Greek letters are used in accordance with common practice with "trivial" names of aliphatic acids, aldehydes, etc , and for some side chains The numbering of each parent ring system is shown by ring formulas in the index under its name This numbering conforms to the "Proposed International Rules for Numbering Organic Ring Systems"[1] with the following exceptions acridine, anthracene, carbazole (isocarbazole), cyclopenta[*a*]phenanthrene, phenanthrene, purine (β purine), xanthene (isoxanthene)

10. When two or more numberings are equally indicated, that one is chosen which gives the smallest number or numbers for the *chief function, then for double bonds* if these must be regarded, *then for triple bonds, then for point of attachment* (doubled molecules), *then for substituents*

11 Numbers and letters enclosed in brackets within the name of a parent ring system are used for distinguishing isomers [2]

12 Numbers in parentheses are used to indicate the position of entering hydrogen necessary to the existence of the compound, thus, 4(3)-quinolone is equivalent to 3,4 dihydro-4-oxoquinoline

13 Doubled molecules or radicals are indicated by names commencing with *bi-* (as, *o,o'*-biphenol, biphenyl, $\Delta^{1,1'}$-bipiperidine) *Bis-, tris-, tetrakis-, etc ,* are used before complex expressions, as, bis(dimethylamino)-

In using the *cross references*, the *general* nature of them should be kept in mind, thus, the references *"Benzene, ethoxy* See *Phenetole"* is applicable not only to this compound itself but to derivatives, which are indexed under it rather than under *Benzene*

[1] Patterson and Curran *J Am Chem Soc* **39** 1621-38(1917)

[2] For the principles used in naming certain parent ring systems and especially in distinguishing isomeric forms by the use of bracketed numbers and letters in the middle of the name, see Patterson, *J. Am Chem Soc* **50** 3074-87(1928)

[3] This order is an attempt to express not the relative chemical importance of functions but general usage in selecting one of them for the ending of the name For a study of the literature on this question, see Patterson *Rec trav chim* **48** 1012-17(1929)

[1] Patterson, *J Am Chem Soc* **47**, 543-61(1925)

[2] Patterson, *J Am Chem Soc* **50** 3083(1928)

NOTE. Since Volume 31 marked the beginning of a new collective-index period a number of modifications of previous practice which had been waiting for adoption were introduced in the index They were made in order that the system may be rendered more consistent and especially that it may conform as nearly as possible to the rules of the Definitive Report of the International Committee on Organic Nomenclature [1] These changes have of course applied in the Volume 33 index also

The changes are indicated in the index itself by cross references, explanations under headings, and new numberings under the names of parent ring systems (see 9, above) The principal changes are.

a Greek letters are used more sparingly, Arabic numerals taking their place where confusion would not result.

b Delta (Δ), denoting a double bond, is omitted where possible

c Bis is used only before complex expressions or when the use of di- would be confusing (e g , Acetic acid, thiobis- becomes Acetic acid, thiodi-)

d The ending *-yne* replaces *-ine* for acetylene hydrocarbons (and *-ynyl* for *-inyl*)

e Carbinol is replaced by *methanol*

f Mercaptans are called *thiols* and Ethyl mercaptan (e. g) becomes Ethanethiol

g β-Butenic acid becomes *3 Buteroic acid*, and so for similar unsaturated acids (likewise, *β Butenaldehyde* becomes *3 Butenal* and *β Butenaldehyde thio-* becomes *3 Butenethiol*)

h Corresponding to the ending "-carboxylic acid," for an *acid halide*, -carbonyl halide is used; for an *aldehyde*, -carboxaldehyde; for a *nitrile*, -carbonitrile

i. Piperidines and *ureides* are in general named as acylpiperidines and acylureas, resp , (e g , Piperidine, 1-acetyl-)

j. Ethyl isocyanide replaces *Ethane, isocyano-* (and so for other simple isocyanides)

k Organometallic compounds are named according to Rule 48 of the Definitive Report (e. g , Lead, tetraethyl-)

l. Phosphorus, arsenic, antimony, and bismuth compounds are named according to revised Rule 34 (*Ind Eng Chem , News Ed* 14, 486(1936))

m. A number of *parent ring systems* are renumbered (see 9, above)

n. The use of *aza, oxa*, etc , before consonants in the names of heterocyclic ring systems causes some changes in spelling (e g , oxadiazine instead of oxdiazine)

o. Spiro systems conform to the Rules for Numbering Hydrocarbons containing two or three spiro atoms are indexed under Dispiro- or Trispiro- (not under Spiro-). The names of simple heterocyclic spiro systems begin with Aza , Oxa-, Dioxa- or the like. Such systems are now included in the Ring Index.

p The systematic use of *brackets* within the names of ring systems is extended

q Changes have been made in the names of *radicals* (see following paragraph) Included in these changes are the replacement of *-al* by *-ylidene* and, for certain acid radicals, of *-yl* by *-oyl* *Oxo* replaces *keto*

ORGANIC RADICALS

Under this heading in the Introduction to the Volume 31 subject index there were listed (1) alphabetically by names and (2) systematically by formulas practically all organic radicals recognized in the system of indexing used by *Chemical Abstracts* This list, as contrasted with earlier ones, was of course affected by the changes mentioned in the preceding paragraphs. This long list cannot be reproduced annually but reprints (obtainable from the editor at 20¢ per copy) are available to those who would find their use more convenient than reference to Volume 31 Changes made since 1937 require alterations in the Volume 31 list as follows

cumal	=	*p*-cumunylidene
cuminal	=	*p*-cumunylidene
cuminyl	=	*p*-$(CH_3)_2CHC_6H_4CH_3$—
cumyl	=	$(CH_3)_2CHC_6H_4$—
cuminylidene	=	*p*-$(CH_3)_2CHC_6H_4CH$=
morpholinyl (from morpholine)	=	C_4H_8NO—

RING INDEX

The following index of *ring complexes* is arranged as shown by the bold face figures· 1-Ring Systems, with single figures indicating simple rings of 3, 5, etc., members, 2 Ring Systems, two figures denoting double rings of 3 and 4, 3 and 5, etc., members, then the triple and still more complex forms. Under each combination of figures the kind and number of atoms in the ring or rings are expressed in formulas These formulas are arranged so that their initial rings are in the same order as in the Formula Index (see Key at the beginning of it). If the initial rings are alike the second rings of the formula are considered, and so on. By this means the reader will be able to learn the name used in the index for the simplest parent compound containing any particular ring or combination of rings and by turning to this name in the index he will find the compound listed and, perhaps, cross references to names of derivatives. Rings which are united but which have no atoms in common (e g , biphenyl) are not regarded as ring complexes nor included in this index "Spiro" compounds, which are characterized by two rings having one atom in common are included

(1) This designates a complex ring of three components, each of six members, (2) the first is heterocyclic, containing five carbon atoms and one nitrogen atom and the other two are carbocyclic rings of six atoms each; (3) parent compounds of this configuration will be found in the in

dex under the five names given. If derivatives are indexed a structural formula will be found with the proper numbering and also appropriate cross references to derivatives having other common names, if any such are in the index.

It should be noted that the classification is made with reference to the smallest rings which, placed together, will constitute the plane formula. Thus norcamphane is treated as a 5,5 complex although a third ring of six members (composed of atoms from the two five membered rings) is also present

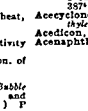
For botanical and zoölogical nomenclature. For the common animals and plants the common names, as *Opossum* and *Wheat*, have been used in accordance with the basic indexing principle that it is best to make entries where most of the index users will look first. For all other animals and plants the scientific names have been used wherever possible. Cross references have usually been entered in both cases, sometimes for several common names. Both types of name (with cross references both ways) have occasionally had to be used for what may be the same organism because of insufficient information, sometimes even in original papers.

For *insects* our authority has been "Common Names of Insects Approved for General Use by the American Association of Economic Entomologists"[1]

[1] *J. Econ. Entom.* 30, 337(1937)

For *bacteria* the classification given in Bergey's "Manual of Determinative Bacteriology," fourth edition, has been followed as far as possible, with numerous cross references.



Alloys. Except for general studies of alloys entries have been made under such headings as *Copper alloys* for each constituent of a given alloy down to small percentage or significance. Alloy trade names (very numerous) have either been entered as headings, as *Duralumin*, with suitable cross references to direct the index user to these names, or have been brought to the beginning of modifying phrases under the alloy heading for the chief constituent in each instance, with cross references entered for the other constituents and for the trade names. "Engineering Alloys," by Normal E Woldman and Albert J Dornblatt (American Society for Metals, 1936) has been used for reference.
